

# MAXIM

## Microprocessor Supervisory Circuits

### General Description

The MAX690 Family of supervisory circuits reduce the complexity and number of components required for power supply monitoring and battery control functions in microprocessor systems. These include  $\mu$ P reset and backup-battery switchover, watchdog timer, CMOS RAM write protection, and power-failure warning. The MAX690 Family significantly improves system reliability and accuracy compared to that obtainable with separate ICs or discrete components.

The MAX690, MAX692 and MAX694 are supplied in 8-pin packages and provide four functions:

- 1) A Reset output during power-up, power-down and brownout conditions.
- 2) Battery backup switching for CMOS RAM, CMOS microprocessor or other low power logic.
- 3) A Reset pulse if the optional watchdog timer has not been toggled within a specified time.
- 4) A 1.3V threshold detector for power fail warning, low battery detection, or to monitor a power supply other than +5V.

The MAX691, MAX693 and MAX695 are supplied in 16-pin packages and perform all MAX690/692/694 functions, plus:

- 1) Write protection of CMOS RAM or EEPROM.
- 2) Adjustable reset and watchdog timeout periods.
- 3) Separate outputs for indicating a watchdog timeout, backup-battery switchover, and low  $V_{CC}$ .

### Applications

Computers  
Controllers  
Intelligent Instruments  
Automotive Systems  
Critical  $\mu$ P Power Monitoring

### Features

- ◆ Precision Voltage Monitor  
4.65V in MAX690, MAX691, MAX694 and MAX695  
4.40V in MAX692 and MAX693
- ◆ Power OK/Reset Time Delay – 50, 200ms, or adjustable
- ◆ Watchdog Timer – 100ms, 1.6 sec, or adjustable
- ◆ Minimum Component Count
- ◆ 1 $\mu$ A Standby Current
- ◆ Battery Backup Power Switching
- ◆ Onboard Gating of Chip Enable Signals
- ◆ Voltage Monitor for Power Fail or Low Battery Warning

### Ordering Information

PART	TEMP. RANGE	PIN-PACKAGE

### ABSOLUTE MAXIMUM RATINGS

Terminal Voltage (with respect to GND)

$V_{CC}$  ..... -0.3V to 6.0V

$V_{BATT}$  ..... -0.3V to 6.0V

All Other Inputs (Note 1) .. -0.3V to ( $V_{OUT} + 0.5V$ )

Input Current

$V_{CC}$  ..... 200mA

$V_{BATT}$  ..... 50mA

GND ..... 20mA

Output Current

$V_{OUT}$  ..... short circuit protected

All Other Outputs ..... 20mA

Rate-of-Rise,  $V_{BATT}$ ,  $V_{CC}$  ..... 100V/ $\mu$ s

Operating Temperature Range

C suffix ..... 0°C to +70°C

E suffix ..... -40°C to +85°C

M suffix ..... -55°C to +125°C

Power Dissipation

8 Pin Plastic DIP

(Derate 5mW/°C above +70°C) ..... 400mW

8 Pin CERDIP

(Derate 8mW/°C above +85°C) ..... 500mW

16 Pin Plastic DIP

(Derate 7mW/°C above +70°C) ..... 600mW

16 Pin Small Outline

(Derate 7mW/°C above +70°C) ..... 600mW

16 Pin CERDIP

(Derate 10mW/°C above +85°C) ..... 600mW

Storage Temperature Range ..... -65°C to +160°C

Lead Temperature (Soldering, 10 seconds) ..... 300°C

Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions above those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum ratings conditions for extended periods may affect device reliability.

### ELECTRICAL CHARACTERISTICS

( $V_{CC}$  = full operating range,  $V_{BATT}$  = 2.8V,  $T_A$  = 25°C, unless otherwise noted.)

**Note 1:** The input voltage limits on PFI and WDI may be exceeded provided the input current is limited to less than 10mA.

**Note 2:** WDI is guaranteed to be in the mid-level (inactive) state if WDI is floating and  $V_{CC}$  is in the operating voltage range. WDI is internally biased to 38% of  $V_{CC}$  with an impedance of approximately 125 kilohms.

## Microprocessor Supervisory Circuits

### Pin Description

NAME	PIN		FUNCTION
	MAX690/ 692/694	MAX691/ 693/695	
V <sub>CC</sub>	2	3	The +5V input.
V <sub>BATT</sub>	8	1	Backup battery input. Connect to Ground if a backup battery is not used.
V <sub>OUT</sub>	1	2	The higher of V <sub>CC</sub> or V <sub>BATT</sub> is internally switched to V <sub>OUT</sub> . Connect V <sub>OUT</sub> to V <sub>CC</sub> if V <sub>OUT</sub> and V <sub>BATT</sub> are not used. Connect a 0.1μF or larger bypass capacitor to V <sub>OUT</sub> .
GND	3	4	0V Ground reference for all signals.
RESET	7	15	RESET goes low whenever V <sub>CC</sub> falls below either the reset voltage threshold or the V <sub>BATT</sub> input voltage. The reset threshold is typically 4.65V for the MAX690/691/694/695, and 4.4V for the MAX692 and MAX693. RESET remains low for 50ms after V <sub>CC</sub> returns to 5V, (except 200ms in MAX694/695). RESET also goes low for 50ms if the Watchdog Timer is enabled but not serviced within its timeout period. The RESET pulse width can be adjusted as shown in Table 1.
WDI	6	11	The watchdog input, WDI, is a three level input. If WDI remains either high or low for longer than the watchdog timeout period, RESET pulses low and WDO goes low. The Watchdog Timer is disabled when WDI is left floating or is driven to mid-supply. The timer resets with each transition at the Watchdog Timer Input.
PFI	4	9	PFI is the non-inverting input to the Power Fail Comparator. When PFI is less than 1.3V, PFO goes low. Connect PFI to GND or V <sub>OUT</sub> when not used. See Figure 1.
PFO	5	10	PFO is the output of the Power Fail Comparator. It goes low when PFI is less than 1.3V. The comparator is turned off and PFO goes low when V <sub>CC</sub> is below V <sub>BATT</sub> .
CE IN	—	13	The input to the CE gating circuit. Connect to GND or V <sub>OUT</sub> if not used.
CE OUT	—	12	CE OUT goes low only when CE IN is low and V <sub>CC</sub> is above the reset threshold (4.65V for MAX691 and MAX695, 4.4V for MAX693). See Figure 6.
BATT ON	—	5	BATT ON goes high when V <sub>OUT</sub> is internally switched to the V <sub>BATT</sub> input. It goes low when V <sub>OUT</sub> is internally switched to V <sub>CC</sub> . The output typically sinks 25mA and can directly drive the base of an external PNP transistor to increase the output current above the 50mA rating of V <sub>OUT</sub> .
LOW LINE	—	6	LOW LINE goes low when V <sub>CC</sub> falls below the reset threshold. It returns high as soon as V <sub>CC</sub> rises above the reset threshold. See Figure 6, Reset Timing.
RESET	—	16	RESET is an active high output. It is the inverse of RESET.
OSC SEL	—	8	When OSC SEL is unconnected or driven high, the internal oscillator sets the reset time delay and watchdog timeout period. When OSC SEL is low, the external oscillator input, OSC IN, is enabled. OSC SEL has a 3μA internal pullup. See Table 1.
OSC IN	—	7	When OSC SEL is low, OSC IN can be driven by an external clock to adjust both the reset delay and the watchdog timeout period. The timing can also be adjusted by connecting an external capacitor to this pin. See Figure 8. When OSC SEL is high or floating, OSC IN selects between fast and slow Watchdog timeout periods.
WDO	—	14	The Watchdog Output, WDO, goes low if WDI remains either high or low for longer than the Watchdog timeout period. WDO is set high by the next transition at WDI. If WDI is unconnected or at mid-supply, WDO remains high. WDO also goes high when LOW LINE goes low.

# Microprocessor Supervisory Circuits

MAX690/91/92/93/94/95

## Typical Applications

### MAX691, MAX693 and MAX695

A typical connection for the MAX691/693/695 is shown in Figure 1. CMOS RAM is powered from  $V_{OUT}$ .  $V_{OUT}$  is internally connected to  $V_{CC}$  when 5V power is present, or to  $V_{BATT}$  when  $V_{CC}$  is less than the battery voltage.  $V_{OUT}$  can supply 50mA from  $V_{CC}$ , but if more current is required, an external PNP transistor can be added. When  $V_{CC}$  is higher than  $V_{BATT}$ , the BATT ON output goes low, providing 25mA of base drive for the external transistor. When  $V_{CC}$  is lower than  $V_{BATT}$ , an internal 200Ω MOSFET connects the backup battery to  $V_{OUT}$ . The quiescent current in the battery backup mode is 1μA maximum when  $V_{CC}$  is between 0V and  $V_{BATT}$ -700mV.

### Reset Output

A voltage detector monitors  $V_{CC}$  and generates a RESET output to hold the microprocessor's Reset line low when  $V_{CC}$  is below 4.65V (4.4V for MAX693). An internal monostable holds RESET low for 50ms\* after  $V_{CC}$  rises above 4.65V (4.4V for MAX693). This prevents repeated toggling of RESET even if the 5V power drops out and recovers with each power line cycle.

The crystal oscillator normally used to generate the clock for microprocessors takes several milliseconds to start. Since most microprocessors need several clock cycles to reset, RESET must be held low until the microprocessor clock oscillator has started. The

MAX690 Family power-up RESET pulse lasts 50ms\* to allow for this oscillator start-up time. The manual reset switch and the 0.1μF capacitor connected to the reset bus can be omitted if manual reset is not needed. An inverted, active high, RESET output is also supplied.

### Power Fail Detector

The MAX691/93/95 issues a non-maskable interrupt (NMI) to the microprocessor when a power failure occurs. The +5V power line is monitored via two external resistors connected to the Power Fail Input (PFI). When the voltage at PFI falls below 1.3V, the Power Fail Output (PFO) drives the processor's NMI input low. If a Power Fail threshold of 4.8V is chosen, the microprocessor will have the time when  $V_{CC}$  fails from 4.8V to 4.65V to save data into RAM. An earlier power fail warning can be generated if the unregulated DC input of the 5V regulator is available for monitoring.

### RAM Write Protection

The MAX691/93/95  $\overline{CE}$  OUT line drives the Chip Select inputs of the CMOS RAM.  $\overline{CE}$  OUT follows  $\overline{CE}$  IN as long as  $V_{CC}$  is above the 4.65V (4.4V for MAX693) reset threshold. If  $V_{CC}$  falls below the reset threshold,  $\overline{CE}$  OUT goes high, independent of the logic level at  $\overline{CE}$  IN. This prevents the microprocessor from writing erroneous data into RAM during power-up, power-down, brownouts, and momentary power interruptions. The LOW LINE output goes low when  $V_{CC}$  falls below 4.65V (4.4V for MAX693).

\*200ms for MAX695

Figure 1. MAX691/693/695 Typical Application

## Microprocessor Supervisory Circuits

### Watchdog Timer

The microprocessor drives the WATCHDOG INPUT (WDI) with an I/O line. When OSC IN and OSC SEL are unconnected, the microprocessor must toggle the WDI pin once every 1.6 seconds to verify proper software execution. If a hardware or software failure occurs such that WDI not toggled, the MAX691/93 will issue a 50ms\* RESET pulse after 1.6 seconds. This typically restarts the microprocessor's power-up routine. A new RESET pulse is issued every 1.6 seconds until WDI is again strobed.

The WATCHDOG OUTPUT (WDO) goes low if the watchdog timer is not serviced within its timeout period. Once WDO goes low it remains low until a transition occurs at WDI. The watchdog timer feature can be disabled by leaving WDI unconnected. OSC IN and OSC SEL also allow other watchdog timing options, as shown in Table 1 and Figure 8.

### MAX690, MAX692 and MAX694

The 8 pin MAX690, MAX692 and MAX694 have most of the features of the MAX691, MAX693 and MAX695.

\*200ms for MAX695

Figure 2 shows the MAX690/692/694 in a typical application. Operation is much the same as with the MAX691/693/695 (Figure 1) but in this case the Power Fail Input (PFI) monitors the unregulated input to the 7805 regulator. The MAX690/694 RESET output goes low when  $V_{CC}$  falls below 4.65V. The RESET output of the MAX692 goes low when  $V_{CC}$  drops below 4.4V.

The current consumption of the battery-backed-up power bus must be less than 50mA. The MAX690/692/694 does not have a BATT ON output to drive an external transistor. The MAX690/92/94 also does not include chip enable gating circuitry that is available on the MAX691/93/95. In many systems though, CE gating is not needed since a low input to the microprocessor RESET line prevents the processor from writing to RAM during power-up and power-down transients.

The MAX690/92/94 watchdog timer has a fixed 1.6 second timeout period. If WDI remains either low or high for more than 1.6 seconds, a RESET pulse is sent to the microprocessor. The watchdog timer is disabled if WDI is left floating.

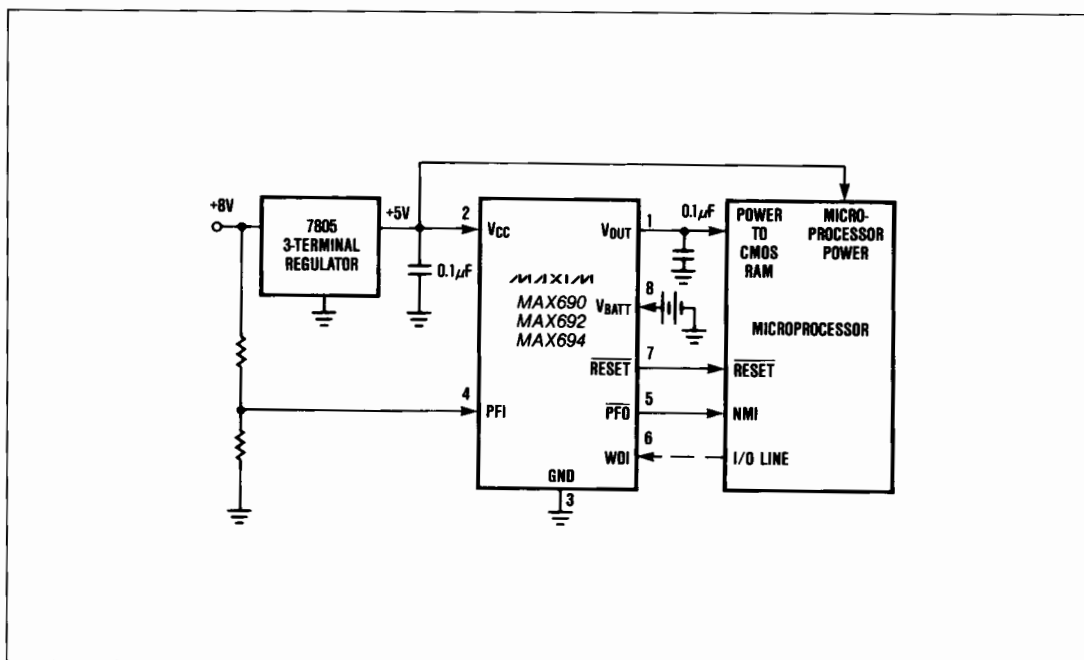

Figure 2. MAX690/692/694 Typical Application

# Microprocessor Supervisory Circuits

MAX690/91/92/93/94/95

## Detailed Description

### Battery-Switchover and $V_{OUT}$

The battery switchover circuit compares  $V_{CC}$  to the  $V_{BATT}$  input, and connects  $V_{OUT}$  to whichever is higher. Switchover occurs when  $V_{CC}$  is 50mV greater than  $V_{BATT}$  as  $V_{CC}$  falls, and when  $V_{CC}$  is 70mV more than  $V_{BATT}$  as  $V_{CC}$  rises (see Figure 4). The switchover comparator has 20mV of hysteresis to prevent repeated, rapid switching if  $V_{CC}$  falls very slowly or remains nearly equal to the battery voltage.

When  $V_{CC}$  is higher than  $V_{BATT}$ ,  $V_{CC}$  is internally switched to  $V_{OUT}$  via a low saturation PNP transistor.  $V_{OUT}$  has 50mA output current capability. Use an external PNP pass transistor in parallel with internal transistor if the output current requirement at  $V_{OUT}$  exceeds 50mA or if a lower  $V_{CC}$ - $V_{OUT}$  voltage differential is desired. The BATT ON output (MAX691/693/695 only) can directly drive the base of the external transistor.

It should be noted that the MAX690/91/92/93/94/95 need only supply the average current drawn by the CMOS RAM if there is adequate filtering. Many RAM data sheets specify a 75mA maximum supply current, but this peak current spike lasts only 100ns. A 0.1 $\mu$ F bypass capacitor at  $V_{OUT}$  supplies the high instantaneous current, while  $V_{OUT}$  need only supply the average load current, which is much less. A capacitance of 0.1 $\mu$ F or greater must be connected to the  $V_{OUT}$  terminal to ensure stability.

A 200 $\Omega$  MOSFET connects the  $V_{BATT}$  input to  $V_{OUT}$

during battery backup. This MOSFET has very low input-to-output differential (dropout voltage) at the low current levels required for battery backup of CMOS RAM or other low power CMOS circuitry. When  $V_{CC}$  equals  $V_{BATT}$  the supply current is typically 12 $\mu$ A. When  $V_{CC}$  is between 0V and ( $V_{BATT}$  - 700mV) the typical supply current is only 600nA typical, 1 $\mu$ A maximum.

The MAX690/MAX691/MAX694/MAX695 operate with battery voltages from 2.0V to 4.25V while the MAX692/MAX693 operate with battery voltages from 2.0V to 4.0V. High value capacitors can also be used for short-term memory backup. External circuitry is required to ensure that the capacitor voltage does not rise above the reset threshold, and that the charging resistor does not discharge the capacitor when in backup mode. The MAX691A and the MAX791 provide solutions requiring fewer external components.

A small charging current of typically 10nA (0.1 $\mu$ A max) flows out of the  $V_{BATT}$  terminal. This current varies with the amount of current that is drawn from  $V_{OUT}$  but its polarity is such that the backup battery is always slightly charged, and is never discharged while  $V_{CC}$  is in its operating voltage range. This extends the shelf life of the backup battery by compensating for its self-discharge current. Also note that this current poses no problem when lithium batteries are used for backup since the maximum charging current (0.1 $\mu$ A) is safe for even the smallest lithium cells.

If the battery-switchover section is not used, connect  $V_{BATT}$  to GND and connect  $V_{OUT}$  to  $V_{CC}$ . Table 2 shows the state of the inputs and output in the low power battery backup mode.

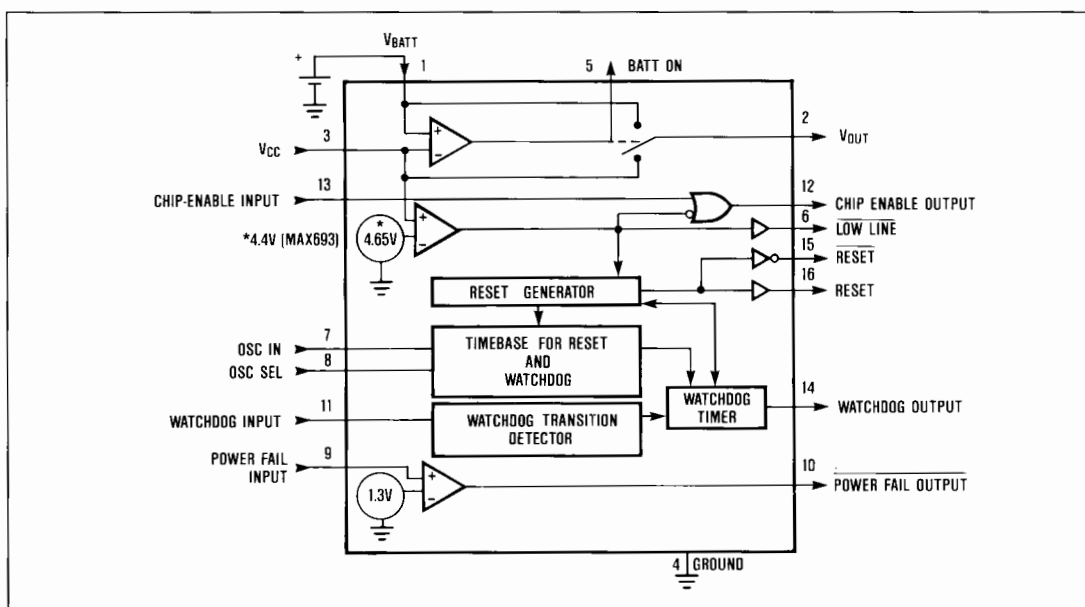

Figure 3. MAX691/693/695 Block Diagram

## Microprocessor Supervisory Circuits

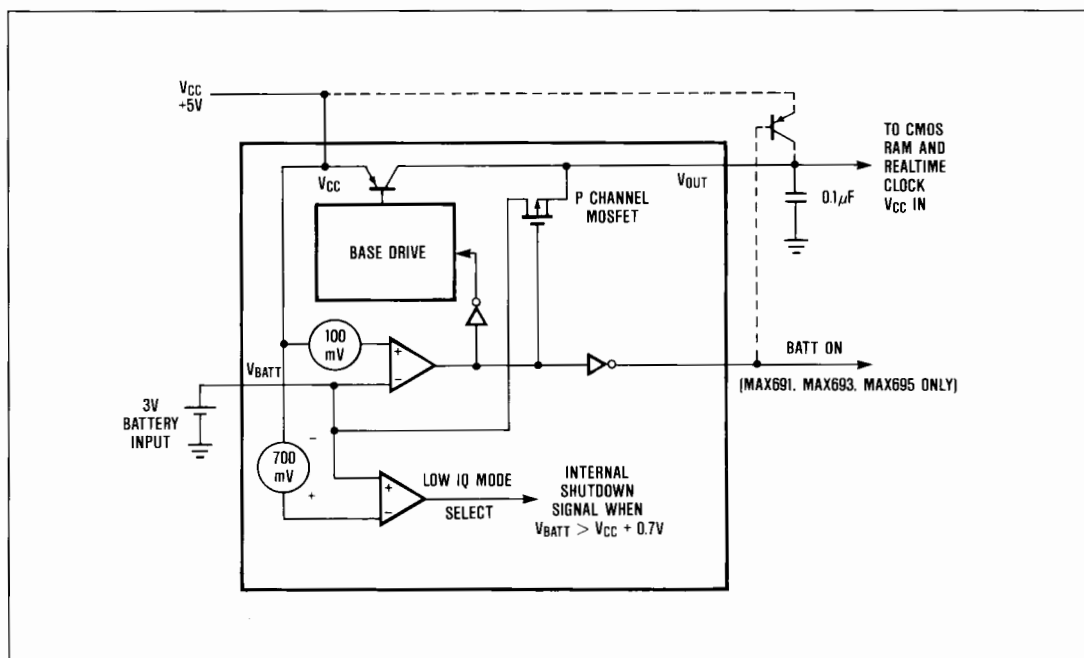

Figure 4. Battery-Switchover Block Diagram

### Reset Output

**RESET** is an active low output which goes low whenever  $V_{CC}$  falls below 4.5V (MAX690/691/694/695) or 4.25V (MAX692/693). It will remain low until  $V_{CC}$  rises above 4.75V (MAX690/691/694/695) or 4.5V (MAX692/693) for 50 milliseconds\*. See Figures 5 and 6.

The guaranteed minimum and maximum thresholds of the MAX690/691/694/695 are 4.5V and 4.75V, while the guaranteed thresholds of the MAX692/693 are 4.25V and 4.5V. The MAX690/691/694/695 is compatible with 5V supplies with a +10%, -5% tolerance while the MAX692/693 is compatible with  $5V \pm 10\%$  supplies. The reset threshold comparator has approximately 50mV of hysteresis, with a nominal threshold of 4.65V in the MAX690/691/694/695, and 4.4V in the MAX692/693.

The response time of the reset voltage comparator is about 100 $\mu$ s.  $V_{CC}$  should be bypassed to ensure that glitches do not activate the RESET output.

RESET also goes low if the Watchdog Timer is enabled and WDI remains either high or low longer than the watchdog timeout period. RESET has an internal 3 $\mu$ A pullup, and can either connect to an open collector Reset bus or directly drive a CMOS gate without an external pullup resistor.

\*200ms for MAX694 and MAX695

### CE Gating and RAM Write Protection

The MAX691, MAX693 and MAX695 use two pins to control the Chip Enable or Write inputs of CMOS RAMs. When  $V_{CC}$  is +5V, CE OUT is a buffered replica of CE IN, with a 50ns propagation delay. If  $V_{CC}$  input falls below 4.65V (4.5V min, 4.75V max) an internal gate forces CE OUT high, independent of CE IN. The MAX693 CE OUT goes high whenever  $V_{CC}$  is below 4.4V (4.25V min, 4.5V max). The CE output of both devices is also forced high when  $V_{CC}$  is less than  $V_{BATT}$ . (See Figure 5.)

CE OUT typically drives the  $\overline{CE}$ ,  $\overline{CS}$ , or  $\overline{Write}$  input of battery backed up CMOS RAM. This ensures the integrity of the data in memory by preventing write operations when  $V_{CC}$  is at an invalid level. Similar protection of EEPROMs can be achieved by using the CE OUT to drive the Store or Write inputs of an EEPROM, EAPROM, or NOVROM.

If the 50ns typical propagation delay of CE OUT is too long, connect CE IN to GND and use the resulting CE OUT to control a high speed external logic gate. A second alternative is to AND the LOW LINE output with the CE or WR signal. An external logic gate and the RESET output of the MAX690/692/694 can also be used for CMOS RAM write protection.

## Microprocessor Supervisory Circuits

MAX690/91/92/93/94/95

Figure 5. Reset Block Diagram

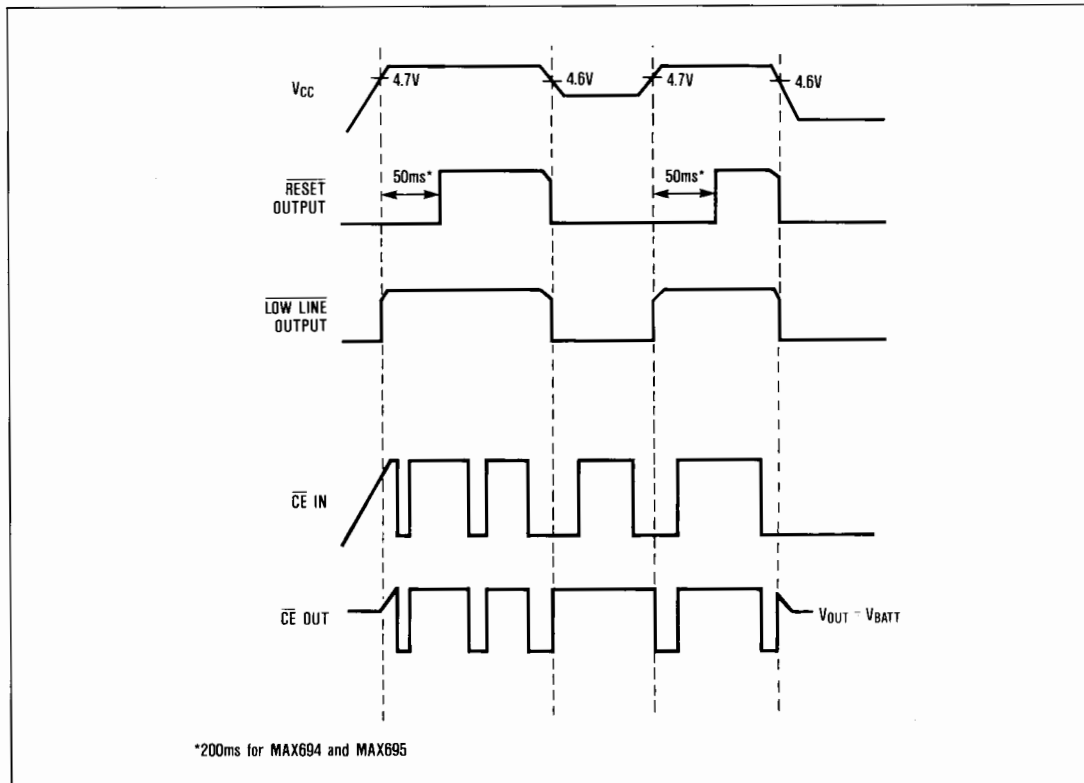

Figure 6. Reset Timing

## Microprocessor Supervisory Circuits

### 1.3V Comparator and Power Fail Warning

The Power Fail Input (PFI) is compared to an internal 1.3V reference. The Power Fail Output (PFO) goes low when the voltage at PFI is less than 1.3V. Typically PFI is driven by an external voltage divider which senses either the unregulated DC input to the system's 5V regulator or the regulated 5V output. The voltage divider ratio can be chosen such that the voltage at PFI falls below 1.3V several milliseconds before the +5V supply falls below 4.75V. PFO is normally used to interrupt the microprocessor so that data can be stored in RAM before  $V_{CC}$  falls below 4.75V and the RESET output goes low (4.5V for MAX692/93).

The Power Fail Detector can also monitor the backup battery to warn of a low battery condition. To conserve battery power, the Power Fail Detector comparator is turned off and PFO is forced low when  $V_{CC}$  is lower than the  $V_{BATT}$  input voltage.

### Watchdog Timer and Oscillator

The watchdog circuit monitors the activity of the microprocessor. If the microprocessor does not toggle the Watchdog Input (WDI) within the selected timeout period, a 50 millisecond\* RESET pulse is generated. Since many systems cannot service the watchdog timer immediately after a reset, the MAX691/693/695 has a longer timeout period after a reset is issued. The normal timeout period becomes effective following the first transition of WDI after RESET has gone high. The watchdog timer is restarted at

the end of Reset, whether the Reset was caused by lack of activity on WDI or by  $V_{CC}$  falling below the reset threshold. If WDI remains either high or low, reset pulses will be issued every 1.6 seconds. The watchdog monitor can be deactivated by floating the Watchdog Input (WDI).

The Watchdog Output (WDO, MAX691/693/695 only) goes low if the watchdog timer "times out" and remains low until set high by the next transition on the watchdog input. WDO is also set high when  $V_{CC}$  goes below the reset threshold.

The watchdog timeout period is fixed at 1.6 seconds and the reset pulse width is fixed at 50ms\* on the 8-pin MAX690, MAX692 and MAX694. The MAX691, MAX693 and MAX695 allow these times to be adjusted per Table 1. Figure 8 shows various oscillator configurations.

The internal oscillator is enabled when OSC SEL is floating. In this mode, OSC IN selects between the 1.6 second and 100ms watchdog timeout periods. In either case, immediately after a reset the timeout period is 1.6 seconds. This gives the microprocessor time to re-initialize the system. If OSC IN is low, then the 100ms watchdog period becomes effective after the first transition of WDI. The software should be written such that the I/O port driving WDI is left in its power-up reset state until the initialization routines are completed and the microprocessor is able to toggle WDI at the minimum watchdog timeout period of 70ms.

\*200ms for MAX694

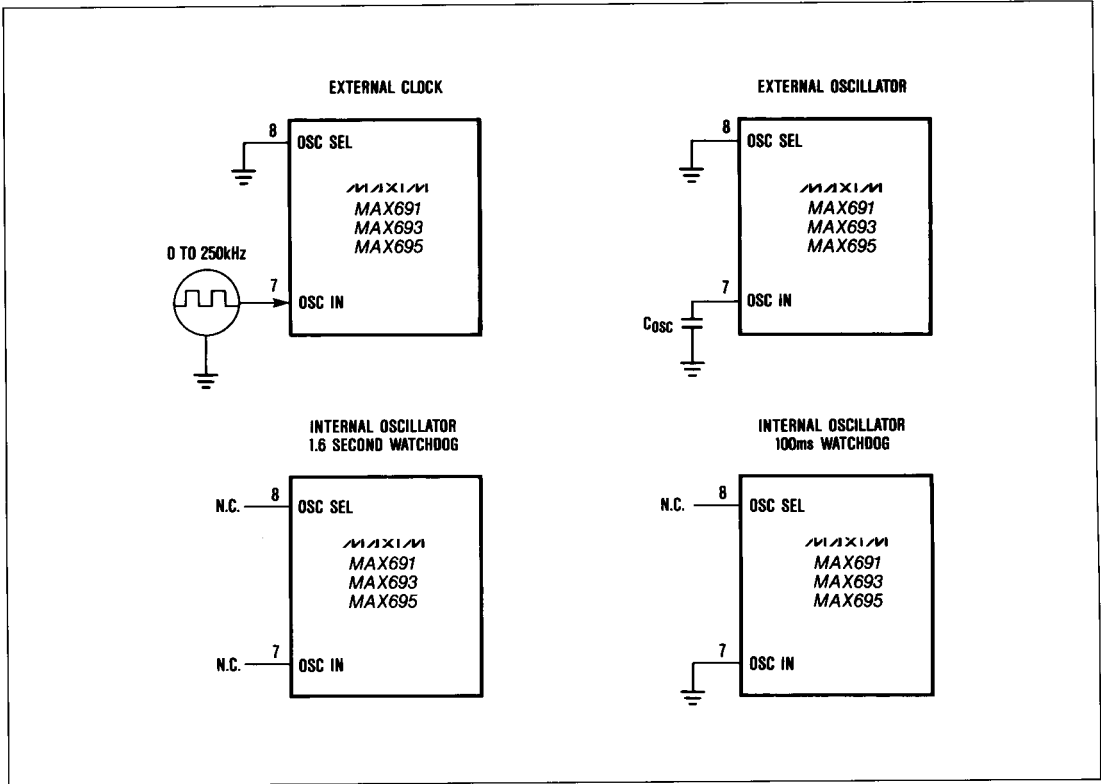

Figure 8. Oscillator Circuits

Table 1. MAX691, MAX693 and MAX695 Reset Pulse Width and Watchdog Timeout Selections

OSC SEL	OSC IN	Watchdog Timeout Period		Reset Timeout Period	
		Normal	Immediately After Reset	MAX691/93	MAX695
Low	External Clock Input	1024 clks	4096 clks	512 clks	2048 clks
Low	External Capacitor	$\frac{400\text{ms}}{47\text{pF}} \times C$	$\frac{1.6 \text{ sec}}{47\text{pF}} \times C$	$\frac{200\text{ms}}{47\text{pF}} \times C$	$\frac{800\text{ms}}{47\text{pF}} \times C$
Floating	Low	100ms	1.6 sec	50ms	200ms
Floating	Floating	1.6 sec	1.6 sec	50ms	200ms

**Note 1:** The MAX690/692/694 watchdog timeout period is fixed at 1.6 seconds nominal, the MAX690/692 reset pulse width is fixed at 50ms nominal and the MAX694 is 200ms nominal.

**Note 2:** When the MAX691 OSC SEL pin is low, OSC IN can be driven by an external clock signal or an external capacitor can be connected between OSC IN and GND. The nominal internal oscillator frequency is 6.55kHz. The nominal oscillator frequency with capacitor is:

$$F_{\text{osc}}(\text{Hz}) = \frac{120,000}{C(\text{pF})}$$

**Note 3:** See Electrical Characteristics Table for minimum and maximum timing values.

## Application Hints

### Other Uses of the Power Fail Detector

In Figure 9 the Power Fail Detector is used to initiate a system reset when  $V_{CC}$  falls to 4.85V. Since the threshold of the Power Fail Detector is not as accurate as the onboard Reset voltage detector, a trimpot must be used to adjust the voltage detection threshold. Both the PFO and RESET outputs have high sink current capability and only 10 $\mu$ A of source current drive. This allows the two outputs to be connected directly to each other in a "wired or" fashion.

The overvoltage detector circuit in Figure 10 resets the microprocessor whenever the nominal 5V  $V_{CC}$  is above 5.5V. The battery monitor circuit (Figure 11) shows the status of the memory backup battery. If desired, the CE OUT can be used to apply a test load to the battery. Since CE OUT is forced high during the battery backup mode, the test load will not be applied to the battery while it is in use, even if the microprocessor is not powered.

### Adding Hysteresis to the Power Fail Comparator

Since the power fail comparator circuit is non-inverting, hysteresis can be added by connecting a resistor between the PFO output and the PFI input as shown in Figure 12. When PFO is low, resistor R3 sinks current from the summing junction at the PFI pin. When PFO is high, the series combination of R3 and R4 source current into the PFI summing junction.

### Alternate Watchdog Input Drive Circuits

The Watchdog feature can be enabled and disabled under program control by driving WDI with a 3-state buffer (Figure 13). The drawback to this circuit is that a software fault may erroneously 3-state the buffer, thereby preventing the MAX690 from detecting that the microprocessor is no longer working. In most cases a better method is to extend the watchdog period rather than disabling the watchdog. See Figure 14. When the control input is high, the OSC SEL pin is low and the watchdog timeout is set by the external capacitor. A 0.01 $\mu$ F capacitor sets a watchdog timeout delay of 100 seconds. When the control input is low, the OSC SEL pin is driven high, selecting the internal oscillator. The 100ms or the 1.6 sec period is chosen, depending on which diode in Figure 14 is used.

## Microprocessor Supervisory Circuits

Table 2. Input and Output Status In Battery Backup Mode

$V_{BATT}, V_{OUT}$	$V_{BATT}$ is connected to $V_{OUT}$ via internal MOSFET.
RESET	Logic low
RESET	Logic high. The open circuit output voltage is equal to $V_{OUT}$ .
LOW LINE	Logic low
BATT ON	Logic high
WDI	WDI is internally disconnected from its internal pullup and does not source or sink current as long as its input voltage is between GND and $V_{OUT}$ . The input voltage does not affect supply current.
WDO	Logic high
PFI	The Power Fail Comparator is turned off and the Power Fail Input voltage has no effect on the Power Fail Output.
PFO	Logic low
CE IN	CE IN is internally disconnected from its internal pullup and does not source or sink current as long as its input voltage is between GND and $V_{OUT}$ . The input voltage does not affect supply current.
CE OUT	Logic high
OSC IN	OSC IN is ignored.
OSC SEL	OSC SEL is ignored.
$V_{CC}$	Approximately 12 $\mu$ A is drawn from the $V_{BATT}$ input when $V_{CC}$ is between $V_{BATT} + 100\text{mV}$ and $V_{BATT} - 700\text{mV}$ . The supply current is 1 $\mu$ A maximum when $V_{CC}$ is less than $V_{BATT} - 700\text{mV}$ .
