

# PBL 3775/1 Dual Stepper Motor Driver

## Description

The PBL 3775/1 is a switch-mode (chopper), constant-current driver IC with two channels, one for each winding of a two-phase stepper motor. The circuit is similar to Ericsson's PBL 3773/1. While several of Ericsson's dual stepper motor drivers are optimized for micro-stepping applications, PBL 3775/1 is equipped with a disable input to simplify half-stepping operation.

The PBL 3775/1 contains a clock oscillator, which is common for both driver channels, a set of comparators and flip-flops implementing the switching control, and two output H-bridges, including recirculation diodes.

Voltage supply requirements are + 5 V for logic and + 10 to + 45 V for the motor.

The close match between the two driver channels guarantees consistent output current ratios and motor positioning accuracy.

## Key Features

- Dual chopper driver in a single package.
- Operation down to -40°C.
- 750 mA continuous output current per channel.
- Low power dissipation, 2.0 W at 2 x 500 mA output current.
- Close matching between channels for high microstepping accuracy.
- Digital filter on chip eliminates external filtering components.
- Plastic 22-pin batwing DIL package, 24-pin SOIC batwing or 28-pin power PLCC. All with lead-frame for heatsinking through PC board copper.

### Notes

- All voltages are with respect to ground. Currents are positive into, negative out of specified terminal.
- All ground pins soldered onto a  $20\text{ cm}^2$  PCB copper area with free air convection,  $T_A = +25^{\circ}\text{C}$ .
- Not covered by final test program.
- Switching duty cycle  $D = 30\%$ ,  $f_s = 23.0\text{ kHz}$ .

Figure 4. Pin configuration.

### Pin Description

SO	DIP	PLCC	Symbol	Description
2	1	[8]	M <sub>B1</sub>	Motor output B, channel 1. Motor current flows from M <sub>A1</sub> to M <sub>B1</sub> when Phase <sub>1</sub> is HIGH.
3	2	[10]	E <sub>1</sub>	Common emitter, channel 1. This pin connects to a sensing resistor R <sub>S</sub> to ground.
4	3	[11]	M <sub>A1</sub>	Motor output A, channel 1. Motor current flows from M <sub>A1</sub> to M <sub>B1</sub> when Phase <sub>1</sub> is HIGH.
5	4	[12]	V <sub>MM1</sub>	Motor supply voltage, channel 1, +10 to +40 V. V <sub>MM1</sub> and V <sub>MM2</sub> should be connected together.
6,7	5, 6,	[1-3, 9,	GND	Ground and negative supply. Note: these pins are used thermally for heat-sinking.
18,19	17, 18	13-17,		Make sure that all ground pins are soldered onto a suitably large copper ground plane for efficient heat sinking.
		28]		
8	7	[18]	V <sub>R1</sub>	Reference voltage, channel 1. Controls the comparator threshold voltage and hence the output current.
9	8	[19]	C <sub>1</sub>	Comparator input channel 1. This input senses the instantaneous voltage across the sensing resistor, filtered by the internal digital filter or an optional external RC network.
10	9	[20]	Phase <sub>1</sub>	Controls the direction of motor current at outputs M <sub>A1</sub> and M <sub>B1</sub> . Motor current flows from M <sub>A1</sub> to M <sub>B1</sub> when Phase <sub>1</sub> is HIGH.
11	10	[21]	Dis <sub>1</sub>	Disable input for channel 1. When HIGH, all four output transistors are turned off, which results in a rapidly decreasing output current to zero.
12	11	[22]	RC	Clock oscillator RC pin. Connect a 12 kohm resistor to V <sub>CC</sub> and a 4 700 pF capacitor to ground to obtain the nominal switching frequency of 23.0 kHz and a digital filter blanking time of 1.0µs.
13	12	[23]	V <sub>CC</sub>	Logic voltage supply, nominally +5 V.
14	13	[24]	Dis <sub>2</sub>	Disable input for channel 2. When HIGH, all four output transistors are turned off, which results in a rapidly decreasing output current to zero.
15	14	[25]	Phase <sub>2</sub>	Controls the direction of motor current at outputs M <sub>A2</sub> and M <sub>B2</sub> . Motor current flows from M <sub>A2</sub> to M <sub>B2</sub> when Phase <sub>2</sub> is HIGH.
16	15	[26]	C <sub>2</sub>	Comparator input channel 2. This input senses the instantaneous voltage across the sensing resistor, filtered by the internal digital filter or an optional external RC network.
17	16	[27]	V <sub>R2</sub>	Reference voltage, channel 2. Controls the comparator threshold voltage and hence the output current.
20	19	[4]	V <sub>MM2</sub>	Motor supply voltage, channel 2, +10 to +40 V. V <sub>MM1</sub> and V <sub>MM2</sub> should be connected together.
21	20	[5]	M <sub>A2</sub>	Motor output A, channel 2. Motor current flows from M <sub>A2</sub> to M <sub>B2</sub> when Phase <sub>2</sub> is HIGH.
22	21	[6]	E <sub>2</sub>	Common emitter, channel 2. This pin connects to a sensing resistor R <sub>S</sub> to ground.
23	22	[7]	M <sub>B2</sub>	Motor output B, channel 2. Motor current flows from M <sub>A2</sub> to M <sub>B2</sub> when Phase <sub>2</sub> is HIGH.
1,24			NC	SO pin 1 & 24 is "Not Connected"

**Functional Description**

Each channel of the PBL 3775/1 consists of the following sections: an output H-bridge with four transistors and four recirculation diodes, capable of driving up to 750 mA continuous current to the motor winding, a logic section that controls the output transistors, an S-R flip-flop, and a comparator. The clock-oscillator is common to both channels.

Constant current control is achieved by switching the output current to the windings. This is done by sensing the peak current through the winding via a current-sensing resistor  $R_s$ , effectively connected in series with the motor winding. As the current increases, a voltage develops across the sensing resistor, which is fed back to the comparator. At the predetermined level, defined by the voltage at the reference input  $V_R$ , the comparator resets the flip-flop, which turns off the upper output transistor. The turn-off of one channel is independent of the other channel. The current decreases until the clock

oscillator triggers the flip-flops of both channels simultaneously, which turns on the output transistors again, and the cycle is repeated.

To prevent erroneous switching due to switching transients at turn-on, the PBL 3775/1 includes a digital filter. The clock oscillator provides a blanking pulse which is used for digital filtering of the voltage transient across the current sensing resistor during turn-on.

The current paths during turn-on, turn-off and phase shift are shown in figure 5.

**Applications Information**

**Current control**

The regulated output current level to the motor winding is determined by the voltage at the reference input and the value of the sensing resistor,  $R_s$ . The peak current through the sensing resistor (and the motor winding) can be expressed as:

$$I_{M,peak} = 0.1 \cdot V_R / R_s \quad [A]$$

With a recommended value of 0.5 ohm for the sensing resistor  $R_s$ , a 2.5 V

reference voltage will produce an output current of approximately 500 mA.  $R_s$  should be selected for maximum motor current. Be sure not to exceed the absolute maximum output current which is 850 mA. Chopping frequency, winding inductance and supply voltage also affect the current, but to much less extent.

For accurate current regulation, the sensing resistor should be a 0.5 - 1.0 W precision resistor, i. e. less than 1% tolerance and low temperature coefficient.

**Current sense filtering**

At turn-on a current spike occurs, due to the recovery of the recirculation diodes and the capacitance of the motor winding. To prevent this spike from resetting the flip-flops through the current sensing comparators, the clock oscillator generates a blanking pulse at turn-on. The blanking pulse disables the comparators for a short time. Thereby any voltage transient across the sensing resistor will be ignored during the blanking time.

Figure 5. Output stage with current paths during turn-on, turn-off and phase shift.

Figure 6. Typical stepper motor driver application with PBL 3775/1.

Low inductance, especially in combination with a high supply voltage, enables high stepping rates. However, to give the same torque capability at low speed, the reduced number of turns in the winding in the low resistive, low inductive motor must be compensated by a higher current. A compromise has to be made. Choose a motor with the lowest possible winding resistance and inductance, that still gives the required torque, and use as high supply voltage as possible, without exceeding the maximum recommended 40 V. Check that the chopping duty cycle does not exceed 50 % at maximum current.

**Heat sinking**

PBL 3775/1 is a power IC, packaged in a power DIP, SO or PLCC package. The ground leads of the package (the batwing) are thermally connected to the chip. External heatsinking is achieved by soldering the ground leads onto a copper ground plane on the PCB.

Maximum continuous output current is heavily dependent on the heatsinking and ambient temperature. Consult figures 8, 9 and 14 to determine the necessary heatsink, or to find the maximum output current under varying conditions.

A copper area of 20 cm<sup>2</sup> (approx. 1.8" x 1.8"), copper foil thickness 35 μm on a 1.6 mm epoxy PCB, permits the circuit to operate at 2 x 450 mA output current, at ambient temperatures up to 85° C.

**Thermal shutdown**

The circuit is equipped with a thermal shutdown function that turns the outputs off at a chip (junction) temperature above 160° C. Normal operation is resumed when the temperature has decreased about 20° C.

**Programming**

Figure 15 shows the different input and output sequences for full-step, half-step and modified halfstep operations. **Full-step mode.** Both windings are energized at all the time with the same current,  $I_{M1} = I_{M2}$ . To make the motor take one step, the current direction (and the magnetic field direction) in one phase is reversed. The next step is then taken when the other phase current reverses. The current changes go through a sequence of four different states which equal four full steps until the initial state is reached again.

**Half-step mode.** In the half-step mode, the current in one winding is brought to zero before a complete current reversal is made. The motor will then have taken two half steps equalling one full step in rotary movement. The cycle is repeated, but on the other phase. A total of eight states are sequenced until the initial state is reached again.

Half-step mode can overcome potential resonance problems. Resonances appear as a sudden loss of torque at one or more distinct stepping rates and must be avoided so as not to lose control of the motor's shaft position.

One disadvantage with the half-step mode is the reduced torque in the half step positions, in which current flows through one winding only. The torque in this position is approximately 70 % of the full step position torque.

**Modified half-step mode.** The torque variations in half step mode will be eliminated if the current is increased about 1.4 times in the halfstep position. A constant torque will further reduce resonances and mechanical noise, resulting in better performance, life expectancy and reliability of the mechanical system.

Modifying the current levels must be done by bringing the reference voltage up (or down) from its nominal value correspondingly. This can be done by using DACs or simple resistor divider networks. The PBL 3775/1 is designed to handle about 1.4 times higher current in one channel on mode, for example 2 x 500 mA in the full-step position, and 1 x 700 mA in the half-step position.
